

Clinical Documentation Assistant

Background

Healthcare professionals spend an estimated **2–3 hours daily** on manual clinical documentation — writing patient notes, summarizing consultations, and organizing medical records. This administrative burden directly contributes to **physician burnout**, reduced patient interaction time, and documentation errors. In high-volume settings like **Indian government hospitals** and **telemedicine platforms**, this problem is significantly amplified.

Problem Statement

There is no accessible, automated system that can take a raw doctor-patient consultation — spanning spoken dialogue, uploaded medical images, and video — and convert it into a **structured, accurate clinical note** without manual intervention.
